Overview

As summarized in Supplementary Data 1, the experimental data obtained for cell type 1 and 2 are used as input parameters (highlighted in grey) to calculate the corresponding p_e .

BASF SE provided the crystalline solid electrolyte β -Li₃PS₄ (1.2×10^{-4} S cm⁻¹) and the L.

The cell casing was manufactured in-house as described in detail previously^{42,43}. The Li | β -Li₃PS₄ | NCM: β -Li₃PS₄ (Li | LPS | NCM:LPS) cells (Supplementary Fig. 1) were asse.

Charge and discharge tests were performed using a VMP-300 Biologic and a MACCOR potentiostat/galvanostat. Cells using lithium as anode material were repeatedly charg.

X-ray photoelectron spectroscopy (XPS) was employed to identify decomposition products and the binding states of the used battery materials. The measurements were carried out using.

Solid-state batteries have the potential to provide higher energy density than traditional lithium-ion batteries¹. The energy density of solid-state batteries developed by NASA has reached 500 Wh/kg, which is almost twice the energy density of the current best electric vehicle battery². Currently, solid-state batteries have an energy density of about 400 watt-hours per kilogram, which is about double the typical energy density of commercial lithium-ion batteries on the market. By 2025, the aim is to achieve an energy density of 450 watt-hours per kilogram³. A combination of the Li-anode and high voltage cathode is expected to give an approximately 30 percent boost to energy density and allow cell level energy density to reach 450-500 Wh/kg and 1000-1200 Wh/L⁴.
