

# Photovoltaic panels are equivalent to the circuit

## System Topology

## Overview

---

PV cells are manufactured as modules for use in installations. Electrically the important parameters for determining the correct installation and performance are: 1. Maximum Power - this is the maximum power output of the PV module (see I-V curve below) 2. Open circuit voltage - the output voltage of the PV cell.

Nominal rated maximum (kWp) power out of a solar array of  $n$  modules, each with maximum power of  $W_p$  at STC is given by: The available solar radiation ( $E_{ma}$ ) varies depending on the time of the year and weather conditions.

As the temperature of PV cells increase, the output drops. This is taken into account in the overall system efficiency ( $\eta$ ), by use of a temperature derating factor  $\eta_{td}$  and is given by: .

To understand the performance of PV modules and arrays it is useful to consider the equivalent circuit. The one shown below is commonly employed. PV module equivalent circuit From the equivalent circuit, we have the.

Efficiency: measures the amount of solar energy falling on the PV cell which is converted to electrical energy Several factors affect the.

An model of an ideal solar cell's p-n junction uses an ideal (whose photogenerated current increases with light intensity) in parallel with a (whose current represents losses). To account for , a resistance and a series resistance are added as . The resulting output current equals the photogenerated curr.

An equivalent circuit model of an ideal solar cell's p-n junction uses an ideal current source (whose photogenerated current increases with light intensity) in parallel with a diode (whose current represents recombination losses). To account for resistive losses, a shunt resistance and a series resistance are added as lumped elements. The resulting output current equals the photogenerated curr...
