

Planets aligned today

Overview

All the planets are visible together in the night sky simultaneously at the moment. iStock Starting from the south-western horizon, the naked eye planets will line-up in the following order: Venus, Mercury, Saturn, Jupiter and Mars. Mercury will be the hardest planet to see, being located in a bright part of the sky. Are all planets shown in the correct zodiac sign?

Only when the orbit realism slider is in the real position (against the tick icon) are all the planets definitely shown in the correct sign of the zodiac. For info on the desktop version controls, click [here](#). This page by default shows the diagrammatic view.

Which planets are visible at night?

Saturn's visible all night. Jupiter and Mars rise in the couple of hours after midnight and are visible in the southeast before sunrise. September 1-7 - If you're in the Northern Hemisphere, you can spot Mercury this week during morning twilight if you can find an unobstructed view toward the east. It appears low in the east just before dawn.

Where can I find a detailed view of a planet?

See the indispensable Observer's Handbook, from the Royal Astronomical Society of Canada. Visit [Stellarium-Web.org](#) for precise views from your location. Almanac: Bright visible planets (rise and set times for your location). Visit [TheSkyLive](#) for precise views from your location.

Why do planets have a slider control?

The reason is that the app has a slider control which changes the orbits of the planets from a diagrammatical view (i.e. all the planets in nice neat, equally separated, circular orbits) to a real view (i.e. all the planets in elliptical orbits with all the inner planets squashed in next to the Sun and the outer planets being widely spaced).

Why do dwarf planets rise above and below the ecliptic?

Dwarf planet positions are also shown - but it should be realised that these objects often rise far above and below the plane of the ecliptic. This is because their orbital planes are tilted with respect to the ecliptic - by more than 40 degrees in some cases.

When will a waning gibbous moon move closer to Jupiter?

Soon after sunset on October 18 and 19, 2024, the waning gibbous moon will move closer to the bright planet Jupiter. The Pleiades star cluster will shine nearby and will be closest to the moon on October 19. Plus the fiery orange star Aldebaran, the Eye of Taurus the Bull, will shine near Jupiter. They'll be visible through dawn.
