

# **Sensitivity factor in power system**

## Overview

---

In power systems, two dominant types of sensitivity relations are defined, namely 1) sensitivity of one electrical variable, such as the voltage  $V_i$  at node  $i$ , with respect to another electrical variable, such as reactive production  $Q_j$  at node  $j$ , and 2) sensitivity of the operating cost  $F$  with respect to such electrical variables as the consumption  $C_i$  at node  $i$  and the production  $P_j$  at node  $j$ . What are sensitivity factors extending power transfer distribution factors to IES?

This article presents sensitivity factors extending Power Transfer Distribution Factors from electric power system analysis to IES. The sensitivity factors include the dynamic behavior of district heating and gas systems as we derive the sensitivity factors from a joined quasi-steady-state power flow calculation.

How do sensitivities affect power flow?

The sensitivities can precisely estimate change of power flow in single networks. The sensitivities reduce the calculation time on average by a factor of eight. In integrated energy systems, adjusting the energy conversion of a coupling unit changes the power flow in the connected energy systems.

Are sensitivity factors more accurate than power flow calculations?

We show that the sensitivity factors are on average ten times faster in estimating a new system state after a unit's power change compared to a power flow calculation. Also, the sensitivity factors can provide good estimates and have a higher accuracy than sensitivity factors which are derived from a steady-state power flow calculation.

What are IES sensitivity factors?

The sensitivity factors include the dynamic behavior of district heating and gas systems as we derive the sensitivity factors from a joined quasi-steady-state power flow calculation. In two case studies we profoundly test the applicability of the IES sensitivity factors, their accuracy, and limitations.

How does a power operator use sensitivities?

The power operator uses these to study and monitor market and system behavior and detect possible problems in the operation. These sensitivities' calculations are also used to determine whether the on-line capacity as indicated in the resource plan is located in the right place in the network to serve the forecast demand.

Are IES sensitivity factors accurate?

In two case studies we profoundly test the applicability of the IES sensitivity factors, their accuracy, and limitations. We show that the sensitivity factors are on average ten times faster in estimating a new system state after a unit's power change compared to a power flow calculation.
