Overview

What is bulk photovoltaic effect?

The bulk photovoltaic effect (BPVE) leads to directed photocurrents and photovoltages in bulk materials. Unlike photovoltages in $p-n$ junction solar cells that are limited by carrier recombination to values below the band-gap energy of the absorbing material, BPVE photovoltages have been shown to greatly exceed the band-gap energy.

What is bulk photovoltaic effect (bpve)?

The bulk photovoltaic effect (BPVE) occurs in solids with broken inversion symmetry and refers to DC generation due to uniform illumination, without the need of heterostructures or interfaces, a feature that is distinct from the traditional photovoltaic effect.

Does bulk photovoltaic effect make solar cells more efficient?

The bulk photovoltaic effect (BPVE), a second-order nonlinear effect that converts light into electricity in solids, has attracted a great deal of interest for power conversion applications and it has been assumed that BPVE can lead to more efficient solar cells. However, the overall efficiency of such devices should be comprehensively understood.

Does bulk photovoltaic effect improve conversion efficiency of optoelectronic devices?

The bulk photovoltaic effect (BPVE) has potential for the realization of high conversion efficiency optoelectronic devices. Here, the authors show that combined in-plane and out-of-plane charge polarizations in MoS₂/black phosphorus heterostructures can enhance the BPVE and reduce the extrinsic response times down to 2.2 ns.

Can low-dimensional piezoelectric materials generate a bulk photovoltaic effect?

Low-dimensional piezoelectric materials have the potential to generate the optoelectronic phenomenon called the bulk photovoltaic effect, which is not limited by the theoretical limit for solar radiation into electricity conversion.

Is there a crossover between two-dimensional and three-dimensional bulk photovoltaic effects?

We also demonstrate a crossover from two-dimensional to three-dimensional bulk photovoltaic effect with the observation of a dramatic decrease in photocurrent density when the thickness of the two-dimensional material exceeds the free path length at around 40 nm.
