

# **Wind turbine bearing lubrication**

## Overview

---

Wind turbines have a power rating often called a nameplate power. For example, 750 kW means that the wind turbine will produce 750 kilowatts (kW) of energy per hour of operation, when running at its maximum performance (see Table 1 for conversions). Wind turbines generate between 0.75 MW and 2.50 MW according to.

The key mechanical and power-generating elements in a wind turbine are a gearbox and the generator to which it is attached. Various designs of wind turbines include the original Dutch.

Considering the extreme environmental and mechanical pressures wind turbines must endure, their reliability is impressive. It is well above that of most conventional generating technologies, and extensive studies show that the best.

Most of the wind turbine gearbox manufacturers have compiled or are in the process of compiling new lubrication specifications. These specifications are more stringent than those.

The gearbox is situated just where the winds are the strongest - as high as 300 feet. In addition, offshore installations encounter rough seas. The engineer will have to gain access up.
