## Overview

What is a gear Hob?

During operation the hob is tilted to helix angle so that its cutting edges remain square with the gear blank. Gear hobbing is a process in which gear is cut by a generating process by rotating the gear blank and the cutter called a hob at the same time with a fixed gearing ratio between hob and gear blank.

What parameters should be controlled in the process of gear hobbing?

Three important parameters are to be controlled in the process of gear hobbing indexing movement, feed rate, and the angle between the axis of gear blank and gear hobbing tool (gear hob). The process of gear hobbing is classified into different types according to the directions of feeding the hob for gear cutting.

What is the process of gear hobbing?

The process of gear hobbing is classified based on the directions of feeding the hob for gear cutting.

How does a gear hobbing machine work?

The hobbing machine can also cut splines and sprockets. The process of gear hobbing involves the use of an automated hob to cut teeth into a circular blank (or flat cylinder) piece of metal, or a “blank” gear. The hobbing machine works to cut the teeth as the gear blank rotates. When is Gear Hobbing Used?

.

How do hobbing machines work?

Gears produced by these machines are made using a rotating tool mounted on an arbor, which was itself mounted on a swiveling axis used to produce a helix angle. The gear blank is mounted on the table of the hobbing machine, and the hob (cutting tool) is fed into the blank, which removes material from

the blank to create the gear teeth.

What are the advantages of gear hobbing process?

The hob is fed tangentially to the face of the gear blank. Advantages of gear hobbing process are described below : (a) Gear hobbing is a fast and continuous process so it is realized as an economical process as compared to other gear generation processes. (b) Lower production cycle time, i.e. faster production rate.
